Assume that you have done an equity valuation of Microsoft. The total value for equity is estimated to be $400 billion and there are 5 billion shares outstanding. What is the value per share?
An added fact

In 1999, Microsoft had 500 million options outstanding, granted to employees over time. These options had an average exercise price of $20 (the current stock price is $80). Estimate the value per share.
The conventional way of getting from equity value to per share value is to divide the equity value by the number of shares outstanding. This approach assumes, however, that common stock is the only equity claim on the firm.

In many firms, there are other equity claims as well including:
- warrants, that are publicly traded
- management and employee options, that have been granted, but do not trade
- conversion options in convertible bonds
- contingent value rights, that are also publicly traded.

The value of these non-stock equity claims has to be subtracted from the value of equity before dividing by the number of shares outstanding.
A warrant is a security issued by a company that provides the holder with the right to buy a share of stock in the company at a fixed price during the life of the warrant.

A warrant is therefore a long term call option on the equity of the firm and can be valued using option pricing models.

Warrants and other equity options issued by the firm are claims on the equity of the firm and have to be treated as equity, which has relevance for:

- estimating debt and equity for the leverage calculation
- estimating per share value from total equity value
Convertible Bonds

- A convertible bond is a bond that can be converted into a pre-determined number of shares, at the option of the bond holder.
- While it generally does not pay to convert at the time of the bond issue, conversion becomes a more attractive option as stock prices increase.
- A convertible bond can be considered to be made up of two securities - a straight bond and a conversion option.
- Firms generally add conversions options to bonds to lower the interest rate paid on the bonds.
The Straight Bond Component

- Embedded in every convertible bond is a straight bond component.
- The easiest way to value the straight bond component is to act as if the conversion option does not exist and value the bond. This can be accomplished as follows:
  - Step 1: Obtain the coupon rate on the convertible bond (which will generally be low because of the conversion option)
  - Step 2: Estimate the interest rate that the company would have had to pay if it had issued a straight bond. This can be obtained either from other bonds that the company has outstanding or from its bond rating.
  - Step 3: Using the maturity of the convertible bond, the coupon rate and the market interest rate, estimate the value of the bond as:
    \[
    \text{Value of Bond} = \text{PV of coupons at market interest rate} + \text{PV of face value of bond at market interest rate}
    \]
- The straight bond component is clearly debt.
Factors in Using Option Pricing Models to Value Convertibles and Warrants

- Option pricing models can be used to value the conversion option with three caveats –
  - conversion options are long term, making the assumptions about constant variance and constant dividend yields much shakier,
  - conversion options result in stock dilution, and
  - conversion options are often exercised before expiration, making it dangerous to use European option pricing models.

- These problems can be partially alleviated by using a binomial option pricing model, allowing for shifts in variance and early exercise, and factoring in the dilution effect.
Steps in Getting to Value Per Share

- **Step 1:** Value the firm, using discounted cash flow or other valuation models.
- **Step 2:** Subtract out the value of the outstanding debt to arrive at the value of equity. Alternatively, skip step 1 and estimate the value of equity directly.
- **Step 3:** Subtract out the market value (or estimated market value) of other equity claims:
  - Value of Warrants = Market Price per Warrant * Number of Warrants
  - Alternatively estimate the value using OPM
  - Value of Conversion Option = Market Value of Convertible Bonds - Value of Straight Debt Portion of Convertible Bonds
- **Step 4:** Divide the remaining value of equity by the number of shares outstanding to get value per share.
An Example: Valuing Sterling Software

The equity in Sterling Software was valued at $2,036 million, based upon projected cash flows.

The firm has two equity options outstanding:

- The firm has 115,000 bonds outstanding, each of which can be converted into 20 shares of stock. The market price of each convertible bond is $1,522 and the face value is $1,000; coupon rate of 5.75%; expires in 8 years; Bond Rating is A-; Interest rate on comparable debt = 7.50%;
- The firm has 1.8 million warrants outstanding, with a strike price of $55 per share; these are trading at $30 per share.
Estimating the Value of Options

- Convertible Debt has market value of $175 million; face value of $115 million; coupon rate of 5.75%; expires in 8 years;
  - Bond Rating is A-; Interest rate on comparable debt = 7.50%;
  - Coupon on Convertible Debt = 0.0575 * 115 million = $6.6125 million
  - Value of Straight Debt Portion of Convertible Debt = $6.6125 (PV of Annuity, 7.5%, 8 years) + $115 million / 1.075^8 = $103.21 million
  - Value of Conversion Option in Debt = Market Value of Convertible Debt - Straight Debt Portion = $175 - $103 = $72 million : Equity
- Value of Warrants = Number of warrants * Warrant Price = 1.8 million warrants * $30 = $54 million
Value Per Share: Sterling Software

Value of Equity = $2,036 million

- Value of Equity in Convertible Debt = $ 72 million
- Value of Equity in Warrants = $ 54 million

Value of Equity in Common Stock = $ 1,910 million

/ Number of Shares outstanding = 25.50 million

Value per Share = $ 74.90
A Comparison to Other Approaches

- The Conservative Approach: Estimate the total number of shares outstanding, including those in the options.
  
  Value of Equity per share = Value of Equity/Fully diluted # of shares
  
  = $ 2,036/ (25.50 + 2.3 + 1.8) = $ 68.78

- The Treasury Stock Approach: Add the expected proceeds from exercise to the numerator before dividing by the number of shares outstanding:

  Value of Equity per share = (Value of Equity + Proceeds from Exercise)/
  Fully diluted number of shares

  = (2036 + 115 + 1.8*55)/(25.5 + 2.3 + 1.8) = $ 76.01
