

## Today's Class

- Talk some more about the CAPM
- Today's new topic: the Efficient Markets Hypothesis (EMH) and performance evaluation
- Midterm review and homework review

1

---

---

---

---

---

---

---

---

## A Review of the CAPM

- A model that links expected returns to risk
  - What risk? "Beta risk".

$$E[R_i] = R_f + \beta_i \cdot (E[R_M] - R_f)$$

- Tells us what the optimal portfolio to invest in is
  - What is it?
  - How do we get that result?

2

---

---

---

---

---

---

---

---

## Three lines

- CML : Capital Market Line
- SML : Security Market Line
- SCL : Security Characteristic Line

3

---

---

---

---

---

---

---

---

## CML

- What is the setting for CALs? What do CALs tell you?
- The CML is just the CAL with the market portfolio in place of the risky asset
  - Market portfolio is a black box
- If I tell you the expected return on a portfolio of a risky asset and the riskfree asset, how will you find the standard deviation of that portfolio?
- How?
  - Painfully

4

---

---

---

---

---

---

---

---

- Given the numbers below, find the standard deviation of a portfolio of the risky asset and the riskless asset which has a mean return of 6%

$$\sigma_{risky} = 10\%, E(r_{risky}) = 12\%, r_f = 5\%$$

$$E(r_p) = 6\%$$

$$E(r_p) = wE(r_{risky}) + (1-w)r_f$$

$$6 = w(12 - 5) + 5$$

$$w = \frac{1}{7}$$

5

---

---

---

---

---

---

---

---

$$\sigma_{risky} = 10\%, E(r_{risky}) = 12\%, r_f = 5\%$$

$$E(r_p) = 6\%$$

$$w = \frac{1}{7}$$

Then

$$\sigma_p^2 = \omega_1^2 \sigma_1^2 + \omega_2^2 \sigma_2^2 + 2\omega_1 \omega_2 \rho_{12} \sigma_1 \sigma_2$$

$$\sigma_p^2 = \omega_{risky}^2 \sigma_{risky}^2 = \left(\frac{1}{7}\right)^2 * 100 = \frac{100}{49}$$

$$\sigma_p = \sqrt{\sigma_p^2} = \frac{10}{7}$$

6

---

---

---

---

---

---

---

---

## The CAL allows us to do this easily

- Use the equation, or

$$E(R_p) = R_f + \left( \frac{[E(R_{\text{risky}}) - R_f]}{\sigma_{\text{risky}}} \right) \sigma_p$$

- Just read it off the graph

7

---

---

---

---

---

---

---

---

8

---

---

---

---

---

---

---

---

## CML

- The CML is just the CAL with the market in place of the risky asset
- The CML is for portfolios of the market and the riskless asset *only*
  - “Efficient portfolios”
- The slope of the CML is the Sharpe ratio of the market portfolio, also called the Market Price of Risk

9

---

---

---

---

---

---

---

---

## The Security Market Line (SML)

- Is the principal equation of the CAPM
- Makes a prediction about what the expected return on a stock/asset/portfolio *should be*, if the CAPM were literally true

$$E[R_i] = R_f + \beta_i \cdot (E[R_M] - R_f)$$

$$E[R_i] - R_f = \beta_i \cdot (E[R_M] - R_f)$$

- We can measure both sides
  - The two sides may not, in practice, be equal
- Alpha: difference between what *your expectation of Ri* and what the CAPM predicts Ri should be

10

---

---

---

---

---

---

---

---

---

---

## Predicted Security Market Line (SML)

11

---

---

---

---

---

---

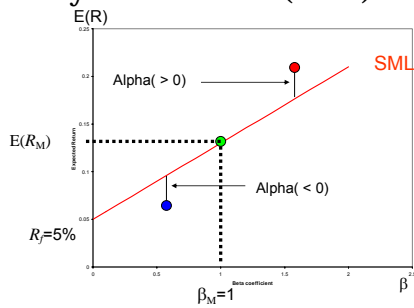

---

---

---

---

## What-might-actually-happen Security Market Line (SML)

12

---

---

---

---

---

---

---

---

---

---

## Applications of the CAPM

- Portfolio choice
  - Market portfolio is the efficient portfolio of risky assets, so you should only hold the market portfolio in combination with riskless assets (e.g. T-bills)
- Tells you what return you might expect from the security - gives benchmark for security analysis
  - So if you form your own estimates of expected returns, you can ask the question, is the return I expect in line with what the CAPM expects?
  - Positive/negative alphas
- Required return used in capital budgeting

13

---

---

---

---

---

---

---

---

## SCL

- We just regress the excess return of the stock on the excess return of the market:

$$R_i - R_f = \alpha_i + \beta_i (R_M - R_f) + e_i$$

- Now take expectations, and notice that  $E(e) = 0$

$$E[R_i - R_f] = \alpha_i + \beta_i E[R_M - R_f]$$

- Suppose I find  $\beta = 2$ ,  $\alpha = 1\%$  and I expect  $R_M - R_f$  to be 10% next period
- What is my (regression's) prediction for  $R_i - R_f$ ?
- What is the CAPM's expectation of  $R_i - R_f$ ?

# Market Efficiency and Performance Evaluation

Andre de Souza

16

---

---

---

---

---

---

---

---

## Outline

- Efficient Market Hypothesis
- Three versions: Weak Form / Semi-strong/Strong Form Efficiency
- Performance evaluation

17

---

---

---

---

---

---

---

---

## Efficient Market Hypothesis (EMH)

- **[Informational] Efficiency = Prices fully reflect all available information.**
- The EMH implies that:
  - a stock price is always at the “fair” level
  - a stock price reacts to news immediately
  - a stock price changes only when the fair level changes
- Stock price changes are unpredictable because no one knows tomorrow’s news.

18

---

---

---

---

---

---

---

---

## EMH: What makes the market efficient?

- If markets were not efficient, investors would trade to take advantage of the inefficiencies.
- Supply and demand and **competition** make it so.
- Efficiency does **not** mean that:
  - Stock prices must go up when a company announces 20% growth.
  - No one can ever outperform the market.
    - Trick is consistently, after transactions costs, and on a risk-adjusted basis

19

---

---

---

---

---

---

---

---

## Efficient Market Hypothesis (EMH)

Three Forms of Efficiency:

- Weak form efficiency
  - prices reflect all information contained in **past trading**
- Semi-strong form efficiency
  - prices reflect all **publicly available** information
- Strong form efficiency
  - prices reflect **all relevant information**, including inside information

These three forms differ in the information set.

20

---

---

---

---

---

---

---

---

## Weak Form Efficiency

- Price reflect all information contained in **history of past prices**
- For example, previous price patterns are part of this information set.
- Technical analysis tries to find the pattern in the history of the price and predict the future price movement. Weak form efficiency means technical analysis should not be useful.

21

---

---

---

---

---

---

---

---

## Semi-Strong Form Efficiency

- Prices reflect all **publicly** available information (not just the information from past price, but also other information publicly available, e.g. earnings announcements, changes in dividend policy, merger news, etc.)
- Studies suggest that abnormal returns to trading on publicly available information are *zero on average* and *disappear quickly*.

22

---

---

---

---

---

---

---

---

## Strong Form Efficiency

- Prices reflect all available information, not only public but also **private** information.
- Empirical findings: corporate insiders earn abnormal returns. Markets are **not** strong form efficient.
- Strong form efficiency → Semi-strong form efficiency → Weak form efficiency

23

---

---

---

---

---

---

---

---

## EMH and Performance

- EMH suggests that it is very difficult to beat the market, especially when transaction costs are taken into consideration
- A good test of EMH is to look at the performance of market professionals and see if their performance is superior to that of a passive index fund or market portfolio

24

---

---

---

---

---

---

---

---

## Performance Evaluation

25

---

---

---

---

---

---

---

---

## Measuring Performance

Suppose we want to measure performance of a strategy (or a portfolio or a mutual fund)

Is it fair to just compare returns?

→ No, we need to adjust for the risk.

→ Why?

Three traditional methods used

- Sharpe Ratio
- Treynor Measure
- Jensen's Alpha Measure

26

---

---

---

---

---

---

---

---

## Risk Adjusted Performance: Sharpe

1) Sharpe Ratio

$$\frac{\bar{r}_p - \bar{r}_f}{\sigma_p}$$

$\bar{r}_p$  = average return of the portfolio (or fund)

$\bar{r}_f$  = risk free rate

$\sigma_p$  = standard deviation of portfolio return

Hard to interpret

27

---

---

---

---

---

---

---

---

**Risk Adjusted Performance:  
Treydor**

2) Treynor Measure 
$$\frac{\bar{r}_p - \bar{r}_f}{\beta_p}$$

$\bar{r}_p$  = average return of the portfolio

$\bar{r}_f$  = risk free rate

$\beta_p = \beta$  for the portfolio

28

---

---

---

---

---

---

---

---

**Risk Adjusted Performance: Jensen**

3) Jensen's Alpha Measure

$$\alpha_p = \bar{r}_p - [ \bar{r}_f + \beta_p ( \bar{r}_m - \bar{r}_f ) ]$$

$\alpha_p$  = alpha for the portfolio

$\bar{r}_p$  = average return of the portfolio

$\beta_p = \beta$  for the portfolio

$\bar{r}_f$  = risk free rate

$\bar{r}_m$  = average return on market portfolio

29

---

---

---

---

---

---

---

---

**Risk Adjusted Performance: an  
example**

- Fund A: average return=0.35, vol=0.42, beta=1.2
- Fund B: average return=0.26, vol=0.30, beta=0.8
- Average return of market portfolio=0.28
- Risk free rate=0.05

Which fund to pick?

- Sharpe measure
- Treynor Measure
- Jensen's Alpha Measure
