

# **MARKET EFFICIENCY: LAYING THE GROUNDWORK**

# WHY MARKET EFFICIENCY MATTERS ..

- The question of whether markets are efficient, and if not, where the inefficiencies lie, is central to investment valuation.
  - If markets are, in fact, efficient, the market price is the best estimate of value, and the process of valuation becomes one of justifying the market price.
  - If markets are not efficient, the market price may deviate from the true value, and the process of valuation is directed towards obtaining a reasonable estimate of this value.
- Market 'inefficiencies' can provide the basis for screening the universe of stocks to come up with a sub-sample that is more likely to have under valued stocks
  - Saves time for the analyst
  - Increases the odds significantly of finding under and over valued stocks.

# WHAT IS AN EFFICIENT MARKET?

- An efficient market is one where the market price is an unbiased estimate of the true value of the investment.
- Implicit in this derivation are several key concepts
  - 
  - Market efficiency does not require that the market price be equal to true value at every point in time. All it requires is that errors in the market price be unbiased, i.e., that prices can be greater than or less than true value, as long as these deviations are random.
  - Randomness implies that there is an equal chance that stocks are under or over valued at any point in time. If the deviations of market price from true value are random, it follows that no group of investors should be able to consistently find under or over valued stocks using any investment strategy.

# DEFINITIONS OF MARKET EFFICIENCY

- Definitions of market efficiency have to be specific not only about the market that is being considered but also the investor group that is covered.
  - It is extremely unlikely that all markets are efficient to all investors, but it is entirely possible that a particular market (for instance, the New York Stock Exchange) is efficient with respect to the average investor.
  - It is possible that some markets are efficient while others are not, and that a market is efficient with respect to some investors and not to others. This is a direct consequence of differential tax rates and transactions costs, which confer advantages on some investors relative to others.
- Definitions of market efficiency are also linked up with assumptions about what information is available to investors and reflected in the price.

# INFORMATION AND MARKET EFFICIENCY

- Under weak form efficiency, the current price reflects the information contained in all past prices, suggesting that charts and technical analyses that use past prices alone would not be useful in finding under valued stocks.
- Under semi-strong form efficiency, the current price reflects the information contained not only in past prices but all public information (including financial statements and news reports) and no approach that was predicated on using and massaging this information would be useful in finding under valued stocks.
- Under strong form efficiency, the current price reflects all information, public as well as private, and no investors will be able to consistently find under valued stocks.

# IMPLICATIONS OF MARKET EFFICIENCY

- No group of investors should be able to consistently beat the market using a common investment strategy.
- An efficient market would also carry negative implications for many investment strategies and actions that are taken for granted –
  - a. In an efficient market, equity research and valuation would be a costly task that provided no benefits. The odds of finding an undervalued stock should be random (50/50). At best, the benefits from information collection and equity research would cover the costs of doing the research.
  - b. In an efficient market, a strategy of randomly diversifying across stocks or indexing to the market, carrying little or no information cost and minimal execution costs, would be superior to any other strategy, that created larger information and execution costs. There would be no value added by portfolio managers and investment strategists.
  - c. In an efficient market, a strategy of minimizing trading, i.e., creating a portfolio and not trading unless cash was needed, would be superior to a strategy that required frequent trading.

# WHAT MARKET EFFICIENCY DOES NOT IMPLY..

- An efficient market does not imply that -
  - (a) stock prices cannot deviate from true value; in fact, there can be large deviations from true value. The deviations do have to be random.
  - (b) no investor will 'beat' the market in any time period. To the contrary, approximately half of all investors, prior to transactions costs, should beat the market in any period.
  - (c) no group of investors will beat the market in the long term. Given the number of investors in financial markets, the laws of probability would suggest that a fairly large number are going to beat the market consistently over long periods, not because of their investment strategies but because they are lucky.
- In an efficient market, the expected returns from any investment will be consistent with the risk of that investment over the long term, though there may be deviations from these expected returns in the short term.

# NECESSARY CONDITIONS FOR MARKET EFFICIENCY

- Markets do not become efficient automatically. It is the actions of investors, sensing bargains and putting into effect schemes to beat the market, that make markets efficient.
- The necessary conditions for a market inefficiency to be eliminated are as follows -
  - (1) The market inefficiency should provide the basis for a scheme to beat the market and earn excess returns. For this to hold true -
    - (a) The asset (or assets) which is the source of the inefficiency has to be traded.
    - (b) The transactions costs of executing the scheme have to be smaller than the expected profits from the scheme.
  - (2) There should be profit maximizing investors who
    - (a) recognize the 'potential for excess return'
    - (b) can replicate the beat the market beating scheme
    - (c) have the resources to trade until the inefficiency disappears

# GENERAL PROPOSITIONS ABOUT MARKET EFFICIENCY

Proposition 1: The probability of finding inefficiencies in an asset market decreases as the ease of trading on the asset increases. You are more likely to find mispriced assets in markets/assets where there is less trading.

Proposition 2: The probability of finding an inefficiency in an asset market increases as the transactions and information cost of exploiting the inefficiency increases.

Proposition 3: The speed with which an inefficiency is resolved will be directly related to how easily the scheme to exploit the inefficiency can be replicated by other investors.

# **EFFICIENT MARKETS AND PROFIT-SEEKING INVESTORS: THE INTERNAL CONTRADICTION**

- There is an internal contradiction in claiming that there is no possibility of beating the market in an efficient market and then requiring profit-maximizing investors to constantly seek out ways of beating the market and thus making it efficient.
- If markets were, in fact, efficient, investors would stop looking for inefficiencies, which would lead to markets becoming inefficient again.
- It makes sense to think about an efficient market as a self-correcting mechanism, where inefficiencies appear at regular intervals

# BEHAVIORAL FINANCE'S CHALLENGE TO EFFICIENT MARKETS

- Underlying the notion of efficient markets is the belief that investors are for the most part rational and even when not so, that irrationalities cancel out in the aggregate.
- A subset of economists, with backing from psychologists, point to the patterns that are observable in stock prices (that we will talk about in more depth in the next section), the recurrence of price bubbles in different asset markets and the reaction to news announcements in markets as backing for their argument.
- Almost all investment philosophies try to exploit one investor irrationality or another and that ironically investor failures in applying these philosophies can be traced back to other irrationalities.

# PSYCHOLOGICAL STUDIES BACKING BEHAVIORAL FINANCE.

1. **Anchors:** When confronted with decisions, it is human nature to begin with the familiar and use it to make judgments
2. **Power of the story:** People look for simple reasons for their decisions, and will often base their decision on whether these reasons exist.
3. **Overconfidence and Intuitive Thinking:** Human beings tend to be opinionated about things they are not well informed on and to make decisions based upon these opinions. They also have a propensity to hindsight bias, i.e., they observe what happens and act as if they knew it was coming all the time.
4. **Herd Behavior:** The tendency of human beings to be swayed by crowds has been long documented (and not just in markets).
5. **Unwillingness to admit mistakes:** It may be human to err, but it is also human to claim not to err. In other words, we are much more willing to claim our successes than we are willing to face up to our failures.

# EMPIRICAL EVIDENCE

- Loss Aversion: Loss aversion refers to the tendency of individuals to prefer avoiding losses to making gains. As a consequence, they will often take an uncertain loss over a certain loss (of equivalent amount).
- House Money Effect: Investors tend to be not only less risk averse but also less careful about assessing it, when playing with other people's money.
- Break Even Effect: Investors who have lost money, become more reckless about risk taking (often taking bad risks and abandoning good sense) to get back what they have already lost.

# **TESTING “MARKET BEATING” SCHEMES AND STRATEGIES**

# TESTING MARKET EFFICIENCY

- Tests of market efficiency look at the whether specific investment strategies earn excess returns, after adjusting for risk. Some tests also account for transactions costs and execution feasibility.
- A test of market efficiency is a joint test of market efficiency and the efficacy of the model used for expected returns. When there is evidence of excess returns in a test of market efficiency, it can indicate that markets are inefficient or that the model used to compute expected returns is wrong or both.

# BENCHMARKS TO ASSESS PERFORMANCE

- Comparison to indices: Compare to returns you would have made by investing in an index, without adjusting for risk.
- Risk and Return Models: You can adjust for risk, when making your comparison:
  - Mean Variance Measures
    - Sharpe Ratio: Average Return / Standard deviation of Returns from Strategy
    - Information Ratio: (Return on Strategy – Return on Index) / Tracking Error versus the Index
  - CAPM based measures
    - Jensen's alpha = Actual return – Expected Return (from CAPM)
    - Treynor Index = (Return on Strategy – Riskfree Rate) / Beta
  - Arbitrage Pricing and Multi-factor Models
  - Proxy and Composite Models

# REVIEWING THE CHOICES...

<i>Performance Evaluation Measure</i>	<i>Computation</i>	<i>Biases</i>
Sharpe Ratio	Average Return on Strategy/ Standard deviation of Returns from Strategy	Against portfolios which are not broadly diversified. Sector specific funds and strategies will be penalized.
Information Ratio	(Return on Strategy – Return on Index)/ Tracking Error versus the Index	Against portfolios that deviate from the index by holding stocks not in the index.
M Squared	Return on Strategy (with riskless investment to have same standard deviation as market) – Return on Market	Same as Sharpe Ratio
Jensen's Alpha	Actual Return – (Riskfree Rate + Beta * (Return on Market – Riskfree rate))	Towards small cap, low PE, low price to book ratio strategies.
Treynor Index	(Return on Strategy – Riskfree Rate)/ Beta	All of the biases of Jensen's alpha but slight tilt towards lower beta strategies.
Excess Return (APM & Multi- factor)	Actual Return – Expected Return (from APM or Multi-factor model)	Mis-measurement of alpha for strategies where the portfolio changes substantially over periods.
Proxy Models	Actual Return – (a + b (Average Market Capitalization) <sub>Portfolio</sub> + c (Average Price to Book Ratio) <sub>Portfolio</sub> )	Against portfolios that try to take advantage of systematic market mispricing of some variables such as market capitalization.

# 1. EVENT STUDY

- An event study is designed to examine market reactions to, and excess returns around specific information events. The information events can be market-wide, such as macro-economic announcements, or firm-specific, such as earnings or dividend announcements.
- The objective is to examine whether the event causes stock prices to move abnormally (up or down).

# STEPS IN CONDUCTING AN EVENT STUDY

1. Specify the “event” that you are testing and identify the “time” the event occurred
2. Returns are collected around these dates for each of the firms in the sample.
  - a. Decide on time intervals (hourly, daily, weekly)
  - b. Determine how many intervals before and after event.
3. Adjust the returns for market performance and risk, i.e., estimate excess or abnormal returns.
4. Estimate the average and standard error in these returns.
5. Check for statistical significance (T statistics, for example)
6. Check for economic significance (Are excess returns large enough to cover execution difficulties and costs?)

# **AN EXAMPLE: THE EFFECTS OF OPTION LISTING ON STOCK PRICES**

- Academics and practitioners have long argued about the consequences of option listing for stock price volatility. On the one hand, there are those who argue that options attract speculators and hence increase stock price volatility. On the other hand, there are others who argue that options increase the available choices for investors and increase the flow of information to financial markets, and thus lead to lower stock price volatility and higher stock prices.
- One way to test these alternative hypotheses is to do an event study, examining the effects of listing options on the underlying stocks' prices.

# THE STEPS IN TESTING THE EFFECT OF LISTING

- Step 1: The date on which the announcement that options would be listed on the CBOE on a particular stock was collected.
- Step 2: The returns of the underlying stock(j) were computed for the ten days prior, the day of, and each of the ten days after announcement
- Step 3: The beta for the stock ( $b_j$ ) was estimated using 100 trading days from before the event and 100 trading days after the event. The returns on the market index ( $R_{mt}$ ) were computed for each of the 21 trading days.
- Step 6: Excess returns were computed for each of the trading days:
  - $ER_{jt} = R_{jt} - b_j R_{mt}$  .....  $t = -10, -9, -8, \dots, +8, +9, +10$
- Step 7: The average and standard error of excess returns across all stocks with option listings were computed for each trading days.

# THE RESULTS OF THE STUDY

<i>Trading Day</i>	<i>Average Excess Return</i>	<i>Cumulative Excess Return</i>	<i>T Statistic</i>
-10	0.17%	0.17%	1.30
-9	0.48%	0.65%	1.66
-8	-0.24%	0.41%	1.43
-7	0.28%	0.69%	1.62
-6	0.04%	0.73%	1.62
-5	-0.46%	0.27%	1.24
-4	-0.26%	0.01%	1.02
-3	-0.11%	-0.10%	0.93
-2	0.26%	0.16%	1.09
-1	0.29%	0.45%	1.28
0	0.01%	0.46%	1.27
1	0.17%	0.63%	1.37
2	0.14%	0.77%	1.44
3	0.04%	0.81%	1.44
4	0.18%	0.99%	1.54
5	0.56%	1.55%	1.88
6	0.22%	1.77%	1.99
7	0.05%	1.82%	2.00
8	-0.13%	1.69%	1.89
9	0.09%	1.78%	1.92
10	0.02%	1.80%	1.91

## 2. PORTFOLIO STUDY

- In some investment strategies, firms with specific characteristics are viewed as more likely to be undervalued, and therefore have excess returns, than firms without these characteristics.
- In these cases, the strategies can be tested by creating portfolios of firms possessing these characteristics at the beginning of a time period, and examining returns over the time period. To ensure that these results are not colored by the idiosyncracies of any one time period, this is repeated for a number of periods.

# STEPS IN DOING A PORTFOLIO STUDY

1. The variable on which firms will be classified is defined, using the investment strategy as a guide. The data on the variable is collected for every firm in the defined universe at the start of the testing period, and firms are classified into portfolios based upon the variable.
2. The returns are collected for each firm in each portfolio for the testing period, and the returns for each portfolio are computed.
3. The “risk” of each portfolio is estimated, using one of the risk and return models.
4. The excess returns and standard errors earned by each portfolio are computed.
5. Use statistical tests to see if the excess returns are different from zero.
6. The extreme portfolios can be matched against each other to see whether they are statistically different.

# TESTING A LOW PE STRATEGY

- Step 1: Using data on PE ratios from the end of 1987, firms on the New York Stock Exchange were classified into five groups, the first group consisting of stocks with the lowest PE ratios and the fifth group consisting of stocks with the highest PE ratios. Firms with negative price-earnings ratios were ignored.
- Step 2: The returns on each portfolio were computed using data from 1988 to 1992. Stocks which went bankrupt or were delisted were assigned a return of -100%.
- Step 3: The betas for each stock in each portfolio were computed using monthly returns from 1983 to 1987, and the average beta for each portfolio was estimated. The portfolios were assumed to be equally weighted.
- Step 4: The returns on the market index was computed from 1988 to 1992.

## TESTING LOW PE STRATEGY (CONTINUED)

- Step 5: The raw returns on each portfolio were computed using data from 1988 to 1992. The following table summarizes the returns each year from 1988 to 1992 for each portfolio.

P/E Class	1988	1989	1990	1991	1992	1988-1992
Lowest	20.65%	30.66%	-1.35%	37.25%	8.22%	19.16%
2	18.56%	33.75%	-3.26%	31.66%	8.51%	18.01%
3	17.01%	28.33%	-3.65%	30.74%	7.70%	15.96%
4	15.56%	30.55%	-4.10%	28.56%	7.10%	15.40%
Highest	15.07%	30.86%	-4.89%	26.51%	6.33%	14.60%
Average	16.81%	31.49%	-3.45%	30.57%	7.58%	16.55%

# LOW PE STRATEGY: EXCESS RETURNS

<i>P/E Class</i>	<i>1988</i>	<i>1989</i>	<i>1990</i>	<i>1991</i>	<i>1992</i>	<i>1988-1992</i>
<i>Lowest</i>	3.84%	-0.83%	2.10%	6.68%	0.64%	2.61%
<i>2</i>	1.75%	2.26%	0.19%	1.09%	1.13%	1.56%
<i>3</i>	0.20%	-3.15%	-0.20%	0.17%	0.12%	-0.59%
<i>4</i>	-1.25%	-0.94%	-0.65%	-1.99%	-0.48%	-1.15%
<i>Highest</i>	-1.74%	-0.63%	-1.44%	-4.06%	-1.25%	-1.95%

### 3. REGRESSIONS

- One of the limitations of portfolio studies is that they become increasingly unwieldy, as the number of variables that you use in your strategy increases.
- The other problem with portfolio studies is that you group firms into classes and ignore differences across firms within each class. Thus, the stocks in the lowest PE ratio class may have PE ratios that range from the 4 to 12.
- If you believe that these differences may affect the expected returns on your strategy, you could get a better measure of the relationship by running a multiple regression. Your dependent variable would be the returns on stocks and the independent variables would include the variables that form your strategy.

# STEP 1: IDENTIFY YOUR DEPENDENT VARIABLE

- This is the variable that you are trying to explain. In most investment schemes, it will be a measure of the return you would make on the investment but you have to make at least two judgments.
  - The first is whether you plan to use total returns or excess returns; with the latter, you would adjust the returns for risk and market performance, using one of the measures discussed earlier in the chapter.
  - The second decision you have to make is on the return interval you will be using – monthly, quarterly, annual or five-year, for instance. This choice will be determined both by your investment strategy – long-term strategies require long-term returns – and the ease with which you can get data on your independent variables for the intervals. For instance, if you use accounting variables such as earnings or book value as independent variables, you will be able to get updates only once every quarter for these variables.

## **STEP 2: DECIDE ON MEASURES THE VARIABLES THAT YOU ARE TESTING**

- In this step, you will have to go beyond qualitative variables and come up with quantitative measures. For instance, if you one of the characteristics that you are looking for high growth, you have to choose your measure of growth - growth in earnings or revenues, growth in the past or expected future growth.
- The information on these variables has to be collected at the beginning of your testing period rather than the end. In other words, if you are looking at returns in 2000, you have to measure growth at the beginning of 2000.

# STEP 3: CHECK FOR THE NATURE OF THE RELATIONSHIP

Panel A: Linear Relationship

Panel B: Non-linear Relationship

## STEP 4: RUN THE REGRESSION

- The regression can either be run
  - Across firms or markets at a point in time: this is called a cross sectional regression.
  - For a market across a number of years: this is called a time series regression.
- Once you run the regression, you have to pass it through the tests for statistical significance. In other words, even if all of the coefficients have the right signs, you have to check to ensure that they are significantly different from zero.
  - In most regressions, statistical significance is estimated with a t statistic for each coefficient. This t statistic is computed by dividing the coefficient by the standard error of the coefficient.
  - You can also compute an F statistic to measure whether the regression collectively yield statistically significant results.

# THE CARDINAL SINS IN TESTING STRATEGIES

1. Using 'anecdotal evidence': Anecdotes can be tailored to come to any conclusion.
2. No holdout periods: An investment scheme should always be tested out on a time period different from the one it is extracted from or on a universe different from the one used to derive the scheme.
3. Sampling Biases: If your sampling is biased, it can provide results that are not true in the larger universe.
4. Failure to control for market performance: When the overall market is doing well (badly), all strategies look good (bad).
5. Failure to control for risk: A failure to control for risk leads to a bias towards accepting high-risk investment schemes and rejecting low-risk investment schemes.
6. Mistaking correlation for causation: Statistical tests often present evidence of correlation, rather than causation.

## SOME LESSER SINS

1. Data Mining: The easy access to huge amounts of data is a double-edged sword. When you relate stock returns to hundreds of variables, you are bound to find some that seem to predict returns, simply by chance.

2. Survivor or Survival Bias: If you start with an existing universe of publicly traded companies and work back through time, you create a bias since you eliminate firms that failed during the period. If the tested strategy is susceptible to picking firms with high bankruptcy risk, this may lead to an overstatement of returns on the scheme.

3. Not allowing for Transactions Costs: Some investment schemes are more expensive than others because of transactions costs - execution fees, bid-ask spreads and price impact.

4. Not allowing for difficulties in execution: Some strategies look good on paper but are difficult to execute in practice, either because of impediments to trading or because trading creates a price impact.

# A SKEPTIC'S GUIDE TO INVESTMENT STRATEGIES

1. Can the investment strategy be tested/implemented?
2. If the strategy can be tested, is the test that has been devised a fair one of the strategy?
3. Does it pass the economic significance tests?
4. Has it been tried before? There is truth to the saying that almost everything that is marketed as new and different in investing has been tried before, sometimes successfully and sometimes not.
