The digital payment system of MGNREGA was designed to facilitate direct benefit transfers to workers. However, despite its advantages, it has faced several challenges. One of the main issues has been the lack of awareness among the beneficiaries regarding how to use the system. This has led to a significant number of complaints from workers who have not received their wages on time. To address this issue, the Government has taken several steps, such as conducting awareness campaigns and providing training to workers. However, despite these efforts, the problem persists.

Despite its dependence on several parameters, the excess-covidence-fact-forensic system required to assess Covid facilities highlights the criticality of controlling the healthcare system and can provide insights into important factors to control. Healthy beds and oxygen systems lead to a steep jump-up in deaths. This model shows that high death undercounts, however, are limited to short time spans when the capacity is overwhelmed. Therefore, an underreporting bias of 30% over the entire pandemic for the full country is unlikely. For the eight districts we analysed, (three shown here) using described parameters, it is roughly between 3-9.
